Modeling Bottom Shear Stress for Transient Wave Events

Tomas Torsvik, Bergen Center for Computational Science In collaboration with Philip L.-F. Liu, Cornell University

Complexity of Nonlinear Waves Tallinn, October 2009

◆□▶ ◆□▶ ◆□▶ ◆□▶ ● ● ● ●

Wave induced bottom shear stress

- Motivation: Provide an accurate description of the bottom shear stress induced by long waves propagating in shallow water.
- 1. Accurate boundary conditions for high order model equations.
 - Energy dissipation
 - Correct wave form and wave speed
- 2. Calculation of bedload sediment transport fluxes.
 - Morphological changes in bathymetry due to periodic or transient waves.

(ロ) (同) (三) (三) (三) (○) (○)

Wave induced bottom shear stress

- Motivation: Provide an accurate description of the bottom shear stress induced by long waves propagating in shallow water.
- 1. Accurate boundary conditions for high order model equations.
 - Energy dissipation
 - Correct wave form and wave speed
- 2. Calculation of bedload sediment transport fluxes.
 - Morphological changes in bathymetry due to periodic or transient waves.

- $\zeta =$ free surface displacement h = constant water depth
- $\alpha =$ width of boundary layer

 α

- Rotational motion confined to the bottom boundary layer. Flow in core region assumed to be irrotational.
- Dimensionless parameters:

$$\epsilon = \frac{a_0}{h} \qquad \text{Nonlinear effect}$$

$$\mu = \frac{h}{\lambda} \qquad \text{Wave dispersion}$$

$$\epsilon^2 = \frac{\nu}{\lambda\sqrt{gh}} \qquad \text{Viscous effects } (\nu = \text{eddy viscosity})$$

Assume weak viscous effects:

$$\mathcal{O}(\alpha) \approx \mathcal{O}(\mu^4) \approx \mathcal{O}(\epsilon^2) \ll 1$$

Boundary layer analysis

- Introduce the stretched vertical coordinate: $\eta = \frac{z+h}{\alpha/\mu}$.
- Leading-order (linearized) momentum equation for horizontal rotational velocity component ur:

$$\frac{\partial \mathbf{u}_r}{\partial t} = \frac{\partial^2 \mathbf{u}_r}{\partial \eta^2}$$

Initial and boundary conditions:

$$\mathbf{u}_{r}(\mathbf{x},\eta,0) = 0$$

$$\mathbf{u}_{r}(\mathbf{x},0,t) = -\nabla\Phi(\mathbf{x},0,t) \quad \text{(no flux, no slip)}$$

$$\mathbf{u}_{r}(\mathbf{x},\infty,t) = 0$$

$$\Rightarrow \mathbf{u}_{r}(\mathbf{x},\eta,t) = -\frac{\eta}{\sqrt{4\pi}} \int_{0}^{t} \frac{\nabla\Phi(\mathbf{x},z=-h,T)}{(t-T)^{3/2}} e^{-\frac{\eta^{2}}{4(t-T)}} dT$$

< □ > < 同 > < 三 > < 三 > < 三 > < ○ < ○ </p>

Boundary layer analysis

- Irrotational horizontal velocity component at the bottom:
 u_b(x, t) = ∇Φ(x, z = −h, T).
- Bottom shear stress:

$$\tau_b = \left. \frac{\partial \mathbf{u}_r}{\partial \eta} \right|_{\eta=0} = \frac{\mathbf{u}_r(\mathbf{x}, \mathbf{0})}{\sqrt{\pi t}} + \frac{1}{\sqrt{\pi}} \int_0^t \frac{\mathbf{u}_b}{(t-T)^{3/2}} \, dT$$

• Vertical rotational velocity component w_r at $\eta = 0$:

$$w_r(\mathbf{x}, 0, t) = \int_{\eta}^{\infty} \nabla \cdot \mathbf{u}_r(\mathbf{x}, \xi, t) \, d\xi \Big|_{\eta=0}$$
$$= -\frac{1}{\sqrt{\pi}} \int_0^t \frac{\nabla \cdot \mathbf{u}_b}{\sqrt{t-T}} \, dT$$

Equations for the core region

Traditional approach

• Bottom boundary condition:

$$\frac{\partial \Phi}{\partial z} = 0$$
, at $z = -h$.

- Long wave model equations, where $\bar{\boldsymbol{u}}=\text{depth}$ averaged horizontal velocity.

(A)
$$\frac{\partial \zeta}{\partial t} + \nabla \cdot ((h + \epsilon \zeta) \bar{\mathbf{u}}) = \mathcal{O}(\mu^4)$$

(B) $\frac{\partial \bar{\mathbf{u}}}{\partial t} + \epsilon \bar{\mathbf{u}} \cdot \nabla \bar{\mathbf{u}} + \nabla \zeta - \frac{\mu^2}{3} \nabla \nabla \cdot \left(\frac{\partial \bar{\mathbf{u}}}{\partial t}\right)$
 $- C_f |\bar{\mathbf{u}}| \bar{\mathbf{u}} = \mathcal{O}(\mu^4)$

Equations for the core region

Boundary layer approach

- Liu and Orfila¹: Long wave equations including a viscous bottom boundary layer.
- Bottom boundary condition:

$$\frac{\partial \Phi}{\partial z} = \frac{1}{\sqrt{\pi}} \int_0^t \frac{\nabla \cdot \mathbf{u}_b}{\sqrt{t-T}} \, dT \,, \quad \text{at} \quad z = -h \,.$$

• Model equations with a viscous bottom boundary layer.

(A)
$$\frac{\partial \zeta}{\partial t} + \nabla \cdot ((h + \epsilon \zeta) \bar{\mathbf{u}}) - \frac{\alpha}{\mu \sqrt{\pi}} \int_0^t \frac{\nabla \cdot \bar{\mathbf{u}}}{\sqrt{t - \tau}} d\tau = \mathcal{O}(\mu^4)$$

(B) $\frac{\partial \bar{\mathbf{u}}}{\partial t} + \epsilon \bar{\mathbf{u}} \cdot \nabla \bar{\mathbf{u}} + \nabla \zeta - \frac{\mu^2}{3} \nabla \nabla \cdot \left(\frac{\partial \bar{\mathbf{u}}}{\partial t}\right) = \mathcal{O}(\mu^4)$

Comparison with laboratory experiment

Liu et al.²: Combined numerical and experimental study on shoaling solitary waves.

Numerical calculation of viscous effects

- Torsvik and Liu³: "An efficient method for the numerical calculation of viscous effects on transient long-waves."
- The viscous term includes a convolution integral on the form

$$A = \int_0^t \frac{\nabla \cdot \bar{\mathbf{u}}}{\sqrt{t-T}} \, dT \, .$$

• Approximate value of *A* is found by truncating in time and estimating the value of the residual term

$$A = A_T + A_R = \int_{t-t_N}^t \frac{\nabla \cdot \bar{\mathbf{u}}}{\sqrt{t-T}} \, dT + A_R \, .$$

For time step (k + 1) and spatial node *i*:

$$\mathcal{A}_i^{(k+1)} pprox \sum_{j=1}^N C_j
abla \cdot ar{\mathbf{u}}_i^{(k+1-j)} + C_R \, \mathcal{R}_i^{(k)} \,,$$

where

$$C_{1} = \int_{t-\frac{1}{2}\Delta t}^{t} (t-T)^{-\frac{1}{2}} dT,$$

$$C_{j} = \int_{t-(j+\frac{3}{2}\Delta t)}^{t-(j+\frac{1}{2}\Delta t)} (t-T)^{-\frac{1}{2}} dT, \quad j \ge 2,$$

$$R_{i}^{(k)} = A_{i}^{(k)} - \sum_{j=1}^{N-1} C_{j} \nabla \cdot \bar{\mathbf{u}}_{i}^{(k-j)},$$

and C_R must be found empirically.
